DATE OF RELEASE: MARCH 26, 1971 - ATLANTA, GEORGIA 30333

EPIDEMIOLOGIC NOTES AND REPORTS

**FOLLOW-UP ON SEPTICEMIAS ASSOCIATED WITH CONTAMINATED ABBOTT INTRAVENOUS FLUIDS**  
United States

On Mar. 22, 1971, on the basis of evidence presented by the Center for Disease Control, the Food and Drug Administration (FDA) issued an order for the recall of Abbott intravenous fluids and recommended that, "all hospitals and other health care facilities begin an orderly and expeditious shift to infusion products other than Abbott (I)." A survey of other intravenous fluid manufacturers has indicated that recent increments in stocks and manufacturing capabilities of these companies are sufficient to compensate for the recall of the Abbott products.

Since March 13, when the FDA and CDC published a specific set of precautions to be observed when using Abbott infusion products (Special Supplement to MMWR, Vol. 20, No. 9), additional evidence has indicated the necessity for the

recall. As of March 22, additional U.S. hospitals have been discovered that have experienced intravenous (IV) fluid associated septicemias with *Enterobacter cloacae* or Erwinia. All of these hospitals use Abbott IV products. A total of 350 IV-associated septicemias have been detected among these hospitals. The *E. cloacae* was isolated 225 times, and Erwinia was isolated 125 times. Ten of these hospitals have microbiologically examined in-use IV apparatus, and all 10 have discovered *E. cloacae* or Erwinia in such fluids.

 ATLANTA GA 30333

## SEPTICEMIAS – (Continued from front page)

Laboratory investigations have repeatedly isolated the epidemic organisms from the inner cap assemblies of previously unopened Abbott IV bottles; transfer of organisms from contaminated cap liners to fluid has been effected after various cap manipulations. In addition to other mechanisms, transfer of organisms from cap liners to fluid has now been shown to occur under conditions simulating the normal hospital practice of placing additives in the fluid: removing the cap, replacing it, shaking the bottle several times, and standing it upright at room temperature. Organisms have also been isolated from the fluid in eight of 874 bottles after the careful removal of the cap.

The necessity for a recall of the products is also supported by data collected from a telephone survey of 81 randomly selected, non-governmental, acute-care hospitals in the United States with 50 to 400 beds. This survey was conducted on Mar. 22, 1971. Of the 35 hospitals using Abbott IV fluids, 8.6 percent were not aware of an infection problem associated with the use of Abbott solutions, and approximately 25-50 percent of the 35 hospitals were not following one or more of the specific precautions as outlined in Special Supplement (MMWR).

Further investigations are underway to discover which, if any, of the existing types and lots of Abbott fluid might be safe to use and to see if different techniques of production might result in caps free of contamination. It is uncertain when conclusive data on these matters will become available.

Hospitals unable to obtain immediately non-Abbott solutions are advised to follow closely these instructions:

- A. A bottle cap should not be struck or otherwise traumatized to effect removal.
- B. If the cap is not easily removed, the bottle should be discarded.

C. The cap should never be replaced after a bottle is partially or completely opened.

D. Containers should be opened only at the point of use.

E. The contents of the containers should be used immediately after opening.

F. When continuous infusions are needed, change IV apparatus at least every 24 hours, including the tubing.

G. At the first suspicion of clinical septicemia or fever which might be associated with contaminated intravenous fluid, all existing IV apparatus should be removed and microbiologically sampled. If continued IV therapy is necessary, it should be initiated with entirely new equipment and solutions.

H. Report complete (eight digit) lot numbers of all clinically or microbiologically suspect solutions to local or State health departments. Lot numbers are printed on the back of the labels.

Hospitals are urged to review their records of positive blood cultures since Jan. 1, 1970, looking for any isolate of *Erwinia* or for an increasing rate of isolation of *E. cloacae* from patients on intravenous therapy. If either are detected, the data should be transmitted to a local or State health department, regardless of the brand of intravenous therapy used in the hospital.

(Reported by the Bacterial Diseases Branch, Epidemiology Program, CDC.)

## Editorial Note:

Without doubt, many additional hospitals using Abbott fluids have experienced similar, but unrecognized, problems due to this source of infection. It now seems clear that the problem was initially recognized by only a small group of hospitals because of their exceptional alertness and initiative in detecting and pursuing nosocomial infection problems.

## METHEMOGLOBINEMIA – Washington, D.C.

On Mar. 13, 1971, a 42-year-old man from District Heights, Maryland, was entertained at the restaurant of a friend in southeast Washington, D.C. The man, his wife, and the restaurant proprietor were served a meal which consisted of broiled halibut with a cream-and-cheese sauce and garlic bread with butter. Soon after dinner, the patient was noted to be tachypneic and somnolent, and he collapsed shortly thereafter. At the same time, his wife experienced severe nausea and vomiting. They were taken to a local hospital where, in spite of intensive therapy, the man died soon after arrival. His wife was noted to be cyanotic, and her blood specimens were described as chocolate-brown in color. A diagnosis of methemoglobinemia was made, and she was treated with methylene blue. She recovered and was discharged on March 15.

An investigation by local health authorities and the Food and Drug Administration (FDA) showed that the patient and his wife had eaten the fish with sauce and the garlic

bread, while the proprietor had eaten only the fish. The bread had been prepared with butter and garlic, as well as with large quantities of a meat tenderizer which was added for flavoring. Samples of the bread were chemically positive for nitrites. Samples of the meat tenderizer were tested both at the District Laboratories of the Columbia Bureau of Health and the District Office of the FDA. The tenderizer was found to contain crystals of pure nitrite. Further investigation revealed that this product had been recalled in November 1970 because of mislabeling; however, several containers of the product have remained unaccounted for.

(Reported by R. A. McConnaughy, M.D., attending physician, Cafritz Memorial Hospital, Washington, D.C.; the Bureau of Food and Drugs, the Bureau of Disease Control, and the Bureau of Laboratories, Health Services Administration, Department of Human Resources, District of Columbia; the Medical Examiners Office, District of Columbia; and the Baltimore District Office, Food and Drug Administration.)

HUMAN LEPTOSPIROSIS - Texas

On Jan. 16, 1971, a 31-year-old man from Frio County, Texas, experienced myalgia, headache, and fever. Two days later, his headache became worse, and severe bilateral conjunctivitis developed. On January 21, he was admitted to a hospital in Dilley, Texas, with nuchal rigidity, positive Kernig's sign, and a temperature of 101°F. On admission, his white blood cell count was 9,600, and a cerebrospinal fluid examination revealed 220 polymorphonuclear cells and 20 lymphocytes, with normal sugar and protein. There was no evidence of hepatic or renal abnormality. A serum specimen obtained on admission showed microscopic agglutination titers of 1:800 for Leptospiral serotypes *autumnalis* and *pomona*. Agglutination titers for typhoid, paratyphoid, *Brucella abortus*, and *Proteus OX-19* strain were negative.

The patient received a 7-day course of penicillin. His condition improved, and he was discharged 6 days after admission. A serum specimen obtained 12 days after the onset of illness showed titers of 1:12,800 for *pomona* and 1:3,200 for *autumnalis*.

The patient raises hogs and has approximately 24 sows in his breeding herd. The farrowing house has a gravity drainage system for urine and wash water, and this system clogged

frequently. When the man cleaned the clogged drains, he often got his hands and feet wet in the drainage water. In the past 12 months, he lost almost half of his pig crop because of abortions and neonatal deaths. Based on these clinical signs, the hogs were treated with 500 gm of chlorotetracycline per ton of feed for 14 days and were vaccinated with a *pomona* bacterin. The breeding herd was moved to a new facility which had an adequate drainage system.

(Reported by Johnny M. Barton, M.D., Wilson V. Garrett, M.D., private physicians, Dilley, Texas; Frank S. Moffett, D.V.M., veterinarian, Dilley, Texas; E. N. Wilson, M.D., County Health Officer, Frio County, Texas; S. J. Lerro, M.D., Epidemiologist, A. B. Rich, D.V.M., Public Health Veterinarian, M. S. Dickerson, M.D., Chief, Communicable Disease Services, Texas State Department of Health; and an EIS Officer.)

Editorial Note:

Texas reported five cases of human leptospirosis in 1970, eight in 1969, seven in 1968, three in 1967, and eleven in 1966. None of these patients were from Frio County. Of the 35 cases reported since 1966, two were associated with swine.

CONTROL OF TURTLE-ASSOCIATED SALMONELLOSIS - Washington

From 1965 to 1967 in Seattle-King County, Washington, 72 of the 619 (11.6 percent) human salmonellosis cases and 35 of the 362 (9.7 percent) salmonellosis outbreaks were associated with turtles (Table 1). In an effort to control this source of infection, the Washington State Board of Health put into effect a regulation on Jan. 1, 1968, requiring that turtles\* be certified salmonella-free by the chief public health official in the State of origin. This regulation resulted in decreases in the importation of turtles into Washington. A marked decline in the number of turtle-associated salmonellosis cases ensued, such that in the Seattle area from 1968 to 1970, one of the 382 cases (0.3 percent) and one of the 245 outbreaks (0.4 percent) were associated with turtles. The methods of surveillance of salmonellosis in Seattle-King County were constant from 1965 to 1970, and the policy of careful investigation of each case indicates that the regulation has essentially eliminated turtle-associated cases of human salmonellosis in the Seattle area.

(Reported by Herb W. Anderson, B.S., R.S., Environmental Epidemiologist, Donald R. Peterson, M.D., Director of Epidemiology, Seattle-King County Department of Public Health; Jack Allard, Ph.D., Supervisor, Chemical and Physical Hazards Section, Division of Health, and Byron J. Francis, M.D., Chief, Office of Epidemiology, Washington State Department of Social and Health Services.)

Editorial Note:

Turtle-associated salmonellosis cases obviously represent a significant number of the estimated 2 million cases occurring annually in the United States (1) (MMWR, Vol. 20, No. 6). It is important to note that the enforcement of the regulation in Washington has been accomplished without any increase in staff.

†Delayed Report for week ended March 13, 1971.

INTERNATIONAL NOTES  
DIPHTHERIA – United Kingdom

Between Feb. 4 and 18, 1971, four cases of diphtheria were reported in Manchester, England. Three of these patients, a 6-year-old child and two siblings aged 9 and 10 years, were admitted to a local hospital with membranous tonsillitis; none of them were severely ill. The two younger children had never been immunized, and the 10-year-old child had received only a primary course. The fourth case was in a 5-year-old unimmunized child who was admitted to a hospital with myocarditis. Virulent strains of *Corynebacterium diphtheriae*, mitis type, were isolated from the two younger patients with faucial diphtheria and from the patient with myocarditis. These strains (*C. diphtheriae*, mitis type) fermented glucose and maltose, but not starch; they had the unusual property of fermenting sucrose.

Throat and nose swabs were obtained from over 2,000 school and family contacts of the patients. Twenty-six carriers of virulent strains of *C. diphtheriae*, mitis type, were detected and were admitted to hospitals for observation and treatment. All patients and carriers were from the same locality. Over 7,000 children living in the immediate vicinity or attending the local schools were immunized between February 18 and 21.

In 1970, 22 cases of diphtheria, with three deaths, were reported in the Registrar General's Weekly Returns for Eng-

land and Wales, compared with 17 cases, with no deaths, in 1969 and 1968. In Scotland, two cases were reported in 1970, compared with none in 1969 and seven in 1968. Laboratories reported the isolation of *C. diphtheriae* from 17 patients and 11 carriers. One case and six associated carriers were detected in south London in March (B.M.J. 9 May). All of the remaining cases and carriers were found in an outbreak in a hospital for mentally subnormal patients (B.M.J. 4 July). There were 15 cases in this hospital. Although most illnesses were mild, two patients died with laboratory-confirmed diphtheria. There were also two other deaths suspected to have been due to diphtheria. Three members of the staff were infected, one of whom had a mild illness. In December, several more cases and carriers were found in the same hospital, and one unimmunized patient died.

Two strains of *C. ulcerans* were isolated. One was from a 32-year-old woman with severe exudative sore throat. The other was from a girl aged 4 years with tonsillitis. One isolation of *C. ovis* was reported from a man aged 30 with proctitis.

(From notes based on reports to the Public Health Laboratory Service from Public Health and Hospital Laboratories in the United Kingdom and Republic of Ireland, published in the British Medical Journal March 6, 1971.)

The Morbidity and Mortality Weekly Report, circulation 22,800, is published by the Center for Disease Control, Atlanta, Ga.

Director, Center for Disease Control  
Director, Epidemiology Program, CDC  
Editor, MMWR

David J. Sencer, M.D.  
Phillip S. Brachman, M.D.  
Michael B. Gregg, M.D.

The data in this report are provisional, based on weekly telegraphs to CDC by state health departments. The reporting week concludes at close of business on Friday; compiled data on a national basis are officially released to the public on the succeeding Friday.

In addition to the established procedures for reporting morbidity and mortality, the editor welcomes accounts of interesting outbreaks for case investigations of current interest to health officials.
